Because the data needs to travel, SSL is always the recommended security solution. If you haven't installed SSL certificates on your local machine yet, do it asap. While using SSL will encrypt your connections, it will also secure you against IP spoofing attacks. QCA.cert.pem The certificate authority certificate file, PEM encoded If you don't want to manually edit the configuration file, you can choose to install the certificate programmatically using the Apache Configuration interface: `sudo certbot --apache -d domain.com` You will have to set your Apache configuration to use the SSL configuration, and you can do that by following the instructions on the DigitalOcean documentation. Congratulations! You have installed the SSL certificate for your DigitalOcean domain. The key is now kept safe in the `~/.ssh/` directory, the certificate file is in the `/etc/letsencrypt/` directory and the private key is on your local machine. Note: We usually recommend using security keys and not passwords. But, if you are forced to use a password, be sure to change it as soon as you can. (Optional) If you installed the certificates as described, DigitalOcean should have created a file for you with the following content. Doing this will give you a one-time login where you can login with your domain username and your API password. If you need to, you can then logout from your Virtual Machine and log back in with the API password from step 4. To update your API password, you can log into your application dashboard: I would also recommend to remove the default user since this is the only user your application has access to (since it is the only one it can login with). Now we can start the application. To do that, you need to install a local instance of postfix on your server: `sudo apt-get update sudo apt-get install postfix` Then, we can start the application: `docker run -d -P -it --name saladin saladin/postfix-mailer You 1d6a3396d6`
