When downloading the software, you need to sign up for a Creative Cloud account, a service that allows you to access all Adobe apps, including Adobe Photoshop Elements. You can find out more information about subscription plans, pricing and how to sign up here. The Importing Process First, you need to download the file that you want to work on. For Photoshop Elements, this file is commonly.EPS (the PSD file format). But it can be any type of image file you have access to, including PNG, TIF, and PSD files. After you have downloaded the file, you need to open it up. Many image editing software (including Photoshop Elements) will automatically open the file for you. But to manually open it, click on File > Open to bring up the Open dialog, click on the folder that contains your image file, and then click on it once more. Doing this should automatically open the image file for you, and it will bring up a new folder that contains the image. If this is a JPEG image file, there will also be a thumbnail image, as shown below: TIP: If you have an image that you want to start with, try opening it up and saving it as a JPEG file first. This file type will keep the lossy compression data in the file, giving your file a higher quality. Keep in mind that a JPEG file has a much smaller file size when compared to a PSD or PNG. If you are going to be working on the image, opening it up as a JPEG file will keep the file size down. You may lose some of the image quality while converting the file, but the reduced file size is helpful. If there is a different icon next to the picture that you want to work on, it means that 05a79cecff

I am, however, confused about the best way to write code that will perform the same operations on a number of objects of a given type. My example will have two objects, foo and bar. They both have a method extract. When extracted, these methods expect the object to be loaded into a HashMap, whose key is the name of the object. Ideally, I would extract like so: String str = foo.extract(); HashMap map = bar.extract(); That is, these methods would always be invoked on objects of the type that they will be invoked on. However, I don't want to know that foo and bar are both of the same type (I don't have to check the type, but the compiler will most likely not let me pass in an object of type foo if I did). I would like to be able to pass in just a reference to any object, such that this method would extract information from this object. I hope this makes sense. A few times I have written code which creates a Map and then iterates over the entries to extract information from the Map. This is not ideal, as it takes up a lot of memory and is inefficient
